

1. Make sure a temp folder exists at the root of C drive. If not, please create one.
2. Close all Internet Explorer windows
3. Open an elevated command prompt and run the following command: *ipconfig /flushdns*
4. Start tracing, by typing the following command:

*netsh trace start tracefile=c:\temp\internetclient.etl scenario=InternetClient_dbg level=5
capture=yes persistent=yes*

5. From Run window, open *iexplore.exe about:blank*
6. Open the impacted URL.
7. If the issue happens then, stop tracing, by typing the following command:

netsh trace stop

8. If the issue does not reproduce, then also stop the tracing using following command and start again from *Step 2*:

netsh trace stop

9. It will generate few files under C:\Temp, out of them please share the .etl, .cab, outputReset.txt and outputDetect.txt files for analysis. Other files may not be produced for a variety of reasons, getting the ETL file is the essential piece of data.

<Note for Engineer>

If the issue is not specific to a URL, then we should always use example.com to collect the logs. It generates least amount of traffic, so the log becomes light weight with lesser noise and easy to analyze.
